Introduction

The guide describes how to blend two projectors accurately onto a curved surface using the Calibre Warp Generator PC application.

All of the HQView warp and blend models use the same process.

Note about good blending

To successfully blend two or more projectors use matched projectors.
a. The projectors should be the same make and model
b. The lamps should be the same age
c. DLP colour wheels should be designed for video
d. The ‘dynamic gamma’ and ‘dynamic contrast’ applications should be set to off
How to blend projection images on a curved surface

1. Align Projectors Optically
2. Set Scaler functions
3. Set Multiple Units Matrix
4. Set Blend Width
5. Set Blend Curve Type
6. Warp Generator
7. Set Black Level Compensation
8. Set Picture Format
Basic system

1. You need to use one processor for each projector.
2. Shown above, the one video source is distributed to both Calibre processors.
3. The distribution amplifier or splitter is not supplied.

When using a multi-port graphics card in a computer [instead of a DA/splitter] please note:-
1. Auto Zoom will be turned ‘OFF’
2. The outputs on each port need to be configured to provide the section of picture relevant to that part of the projection

**AND**

3. The outputs on each port need to be configured to provide the overlapping parts of the picture that will be used to blend the picture segments together.
Align projectors optically

Figure 1

Figure 1 shows an example of two 4:3 projectors being used to project a single 16:9 image.

The light projected needs to cover the whole of the screen area.

Align the position, zoom and focus of the projectors. Use the built-in test patterns in the Calibre processors.
Set Scaler Functions

From the top menu select ‘System’ then select ‘Menu Settings’ then select ‘Menu Display Time’ and then select ‘Infinite’ to turn off the menu time-out.

Returning to the top menu select ‘Output’ then ‘Display Type’ and set the output resolution to the native resolution of your projector. (It is important to let the Calibre processor do the scaling)

Set the Frame rate to Auto

Set the I/O lock to Auto

Set Multiple Units Matrix

The following is for both Calibre processors in the system

![Figure 2](image)

Figure 2
Figure two shows the menu system in the Calibre scaler.
Set the position in the matrix

3. Tell each processor where it is in the system.
   a. In the top menu (figure 2 above), select ‘multiple unit’

![Figure 3](image)

**Figure 3**
Figure three shows the ‘multiple Unit’ menu.

b. Set the system to match your projector arrangement (2x1 for this example):
   Set ‘units wide’ to 2

![Figure 4](image)

**Figure 4**
Figure 4 shows the representation of two overlapping images on a screen.

c. Tell each processor which projector it is connected to:
   Set horizontal position either 0 or 1 (0 for left hand projector and 1 for right hand projector)

d. Auto Zoom:- If you are using a single source going into a splitter then you will need to leave ‘Auto Zoom’ on.
   If you have content that is already pre-cut and being distributed from source direct to each Scaler then select ‘Auto zoom’ off.
Set Blend Width

In the ‘multiple unit’ menu

e. Choose ‘Blend Curve Type’ menu item and select ‘Align Pattern’ – this turns on the blend width alignment tool

![Figure 5](image)

**Figure 5**
Figure 5 shows two projections side by side displaying the horizontal bar test pattern with blend width alignment tool

1. In the top menu select ‘Input’ and then select ‘test pattern’ input (or press the test pattern key if provided on the front panel)
2. Then select horizontal grey bars test pattern by:-
   a. Exiting the menu system then using the up/down buttons to rotate around the available patterns

Or

b. In the top menu select ‘System’ then item 3 ‘Input Configuration’ then item 4 ‘Test Pattern Setup’ then select ‘Test Pattern’ and select ‘Grey H Bars’.

f. In the ‘Multiple unit’ menu Choose ‘Blend Width’ menu item.
   The default blend width is 200 pixels, adjust the number of pixels to equal the optical overlap. The alignment pattern is designed to make this task visible.

   Do not adjust the blend offset, leave this set to 0.

   The two vertical lighter stripes near the centre of the screen are the blend width alignment tool.
   This is a visible cursor which will move as the blend width is adjusted.
   Line 1 is the left hand edge of the right hand projection
   Line 2 is the right hand edge of the left projection blend region
   Line 3 is the left hand edge of the right projection’s blend region
   Line 4 is the right hand edge of the left hand projection

   Referring to Figure 4 above –
   Adjust line 3 to meet line 1 and adjust line 2 to meet line 4
This adjusts the blend width of each projector so that the shadowed alignment area is equal to the optical overlap.

**Figure 6**
Figure 6 shows the left hand blend width correctly adjusted.

**Figure 7**
Figure 7 shows the view when the blend widths on both scalers are adjusted correctly.

**NB:** It is important to set the number of blend width pixels to the same number for both processors, even if the lines in figure 7 do not quite align.

- do not be concerned if the lines do not quite match the overlap for one projector this indicates that the optical zoom of the projectors is not matched, the blend will still work.
Now change the test pattern to the cross hatch (F) Warp pattern

Green or magenta colour patterns give clear indication of which warp needs adjusting. The blend region is correctly overlaid when the result is white. Inaccurate adjustment can be clearly seen as a coloured fringe around the white.

**Warp the projection image on to a curved surface**

For curved screen and irregular shaped surfaces Calibre have developed a drag and drop ‘Warp Generator’ PC program which calculates warp maps to be uploaded to memories built in to the Calibre processor.

**Download and install the Warp Generator**

Download this application from our web site using the following link and selecting ‘Warp Generator Vx-XX-XXXX’ from the ‘Software’ drop down box http://www.calibreuk.com/product_pages/scalers/hqv-downloads.php

Before you install the warp generator on your PC please check if you have .NET framework version 3.5 installed. This is needed to run the warp generator software. If it is not installed on your PC you may also need to download .NET framework version 3.5 http://www.microsoft.com/en-us/download/details.aspx?id=21 and install this first.

Using a ‘change over’ cable for one processor at a time or both at once via an Ethernet switch or network. Connect your computer to the Calibre processors using the LAN connection.
Open the Warp generator program

Start the Warp Generator and you will see the following screen, open this program multiple times to match number of projectors to make it easier to connect to each unit.

In the top left corner of the screen you will see the ‘Connect’ button. Click on this button and one of the following pop-ups will appear

This will appear if you have previously used the warp generator

This will appear if it is the first you have used the program or if you say ‘no’ to the previous pop-up
Enter the address of the processor (which can be found on the unit itself, System menu – networks settings and take note of the IP address) you wish to connect to and click on ‘Add an Address’
The address will appear in the lower window
Highlight the address in the lower window and click on ‘Connect to Unit’

Once connected press ‘New Grid’ this will present a pop up to name that particular grid i.e. LeftProjector.

The following window will appear.
To explain the functions of the panels please see the following list:-
1. Press the ‘Send’ button to calculate the warp map and send it to the memory slot chosen in ‘6’.

2. Progress of the warp up-load will be reported here.

3. You can set a rotation of the image here, warp and rotation can be achieved simultaneously with this function. You can rotate +/- 180 degrees in one degree steps.

4. An overall magnification or overall reduction in size can be set here.

5. Grid status check.

6. The Calibre processors have 8 memories for warp maps, choose which memory slot you wish to address.

7. You can choose to drag and drop individual points on the grid or here you can choose to move a whole horizontal row, whole vertical columns and other helpful combinations on the mesh.

8. Do not save your changes and exit the warp generator.

9. Undo last change.

10. Increase or decrease the number of point on the grid.

11. Use these arrow keys or the ones on your computer keyboard to move a selected point by the amount specified in 12

12. Set the amount of pixels movement takes place when the arrow keys (11) are pressed

13. Access to additional preset settings

14. Turns the warp on and off to help you see your progress

15. Switches between warp test pattern and last selected video input

16. Applies an overall linear curve +ve or –ve in the horizontal X direction and in the vertical Y direction
   Use together for dome applications

17. Re-do last un-do (item17)

18. Reset the position of all mesh nodes

19. Reset the position of the selected node

20. Exit the Warp Generator and save changes
Set the Warp using the Warp Generator

Start by unticking all boxes in item 7 to turn off the ‘mirror’ adjust and the ‘snap’ options, then you can start adjusting the four corners on each projector, you can then increase the points in your grid to get your curve (10).

Adjust the position of the points with either the mouse or the arrow keys (on screen or keyboard) to positions you think will bring the test pattern correctly onto your screen. Press the SEND button (1) and wait for the result to be seen on the screen and the comment Warp Success to appear at (2).
Note that in the above example the size and shape of the squares are not even across the whole screen. The linearity needs adjustment.

Linearity is achieved by adjusting the centre positions as indicated below. Note the relative sizes of the red rectangles, these should be equal sizes. If they are not equal as in the example below the linearity will be poor.

Continue adjustment looking to achieve an even size of test pattern squares across the whole screen and the overlapping area as closely aligned as possible.

NB: when the Green and Magenta lines are correctly over-laid the colour turns white.

Increase the number of points in the grid (10) to give more detailed adjustment only when you have made all the adjustments you can with the coarse setting.
In the Multiple Unit menu switch the Blend Curve Type to S Curve

Select your video input from either the front panel of the unit or using the Input menu.
Set Picture Format

In main menu select Geometry then Picture Format

Picture Format allows a user to select the displayed aspect ratio where the signal input is different to the display’s natural aspect ratio.

Choose between Standard, Full Screen, Crop or Anamorphic

a. **Standard** preserves the size and aspect ratio of the incoming image. Areas of the display that are un-used are displayed black (letterboxed).

b. **Full Screen** scales the image to the size of the display without preservation of the aspect ratio. Please note that some signals have black borders which will be displayed as black.

c. **Crop** preserves the aspect ratio of the image and scales the image to fill the screen. The smaller axis of the image will fill the space available. The result is that either the top/bottom or right/left areas of the image are cropped.

d. **Anamorphic** scales the input image to display the whole picture in a 16:9 aspect ratio. Areas of the display that are un-used are displayed black (letterboxed).
